

# Meshlets with DataSync

A meshlet is a Perspectium application that helps in integrating Perspectium-supported applications for data storage. Each meshlet is a self-contained application that connects to the Mesh Message Queue Service (MQS) to read and write messages to the queues.

Meshlets will consume messages from a queue and then decrypt the message and convert it to the expected format to save into the target system or database. Once a message is consumed from the Integration Mesh, the message will no longer reside in the queue and once the meshlet has finished processing a message, the message will be gone as the meshlet does not keep any messages long term.

Meshlets are also used with [ServiceBond](#)—read about that [here](#).
